Abstract

This document contains the description of the experiments carried out by SINAI group. We have developed an approach based on several lexical and syntactic measures integrated by means of different machine learning models. More precisely, we have evaluated three features based on lexical similarity and 11 features based on syntactic tree comparison. In spite of the relatively straightforward approach we have obtained more than 60% for accuracy. Since this is our first participation we think we have reached a good result.

1 Approach description

We fill face the textual entailment recognition using Machine Learning methods, i.e. identifying features that characterize the relation between hypothesis and associated text and generating a model using existing entailment judgements that will allow us to provide a new entailment judgement agains unseen pairs text-hypothesis. This approach can be split into the two processes shown in Figures 1 and 2.

In a more formal way, given a text t and an hypothesis h we want to define a function e which takes these two elements as arguments and returns and answer to the entailment question:

$$e(t,h) = \begin{cases} YES & \text{if } h \text{ is entailed by } t \\ NO & \text{otherwise} \end{cases} \quad (1)$$

Now the question is to find that ideal function

Figure 1: Training processes

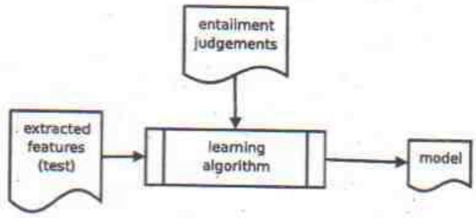

Figure 2: Classification processes

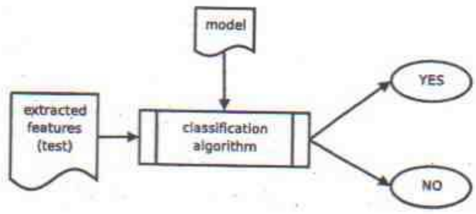

$e(t,h)$. We will approximate this function using a binary classifier:

$$\hat{e}(t,h) = bc(f,m) \quad (2)$$

where
- bc is a binary classifier
- f is a set of *features*
- m is the learned model for the classifier

Therefore, it only remains to select a binary classifier and a feature extraction method. We have performed two experiments with different choices for both decisions. These two experiments are detailed below.

Proceedings of the Workshop on Textual Entailment and Paraphrasing, pages 78–82, Prague, June 2007. ©2007 Association for Computational Linguistics

- **Exp2** uses five features: four lexical similarities ($SIM_{matching}$ + $CSS_{matching}$ + Trigrams + $BIN_{matching}$) and Syntactic tree comparison.
- **Exp3** uses only three lexical similarities ($SIM_{matching}$ + $CSS_{matching}$ + Trigrams).
- **Exp4** uses the four lexical similarities ($SIM_{matching}$ + $CSS_{matching}$ + Trigrams + $BIN_{matching}$)
- **Exp5** uses only three lexical similarities ($SIM_{matching}$ + $CSS_{matching}$ + Trigrams).
- **Exp6** uses four features: three lexical similarities ($SIM_{matching}$ + $CSS_{matching}$ + Trigrams) and Syntactic tree comparison.

As we expected, the best result we have obtained is by means of the integration of the whole of the features available. More surprising is the good result obtained by using lexical features only, even better than experiments based on syntactical features only. On the other hand, we expected that the integration of both sort of features improve significatively the performance of the system, but the improvement respect of lexical features is poor (less than 2%). . Similar topics share similar vocabulary, but not similar syntax at all. Thus, we think we should to investigate semantic features better than the syntactical ones.

3 Conclusions and future work

In spite of the simplicity of the approach, we have obtained remarkable results: each set of features has reported to provide relevant information concerning to the entailment judgement determination. On the other hand, these two approaches can be merged into one single system by using different features all together and feeding with them several binary classifiers that could compose a voting system. We will do that combining TiMBL, SVM and BBR.We expect to improve the performance of the entailment recognizer by this integration.

Finally, we want to implement a hierarchical architecture based on constraint satisfaction networks. The constraints will be given by the set of available features and the maintenance of the integration across the semantic interpretation process.
